### Lifestyle and Dietary Modification

Therapeutic lifestyle change is the cornerstone for reducing risk for Cardiovascular Disease (CVD) and diabetes.

The following recommendations are based on the American Heart Association's dietary and lifestyle guidelines. Consume a dietary pattern that achieves <6% of calories from saturated fat and emphasizes intake of vegetables, fruits and whole grains; includes low-fat dairy products, poultry, fatty fish, legumes, non-tropical vegetable oils and nuts; and limits intake of refined grains, sweets, sugar-sweetened beverages and red meats. Eliminate foods high in trans fat.

If indicated: control blood pressure, reduce weight, engage in smoking cessation and be physically active — work up to getting at least 30 minutes of a moderate intensity physical activity, at least 5 days per week.

• To increase alpha-1 levels it is important to reduce weight, reduce refined carbohydrate intake, eliminate trans fats and increase physical activity.

To improve Fatty Acid Balance results refer to the dietary changes provided in the Fatty Acid Balance interpretation section of this report.

### Statins

According to studies, stating have been shown to reduce cholesterol production, increase LDL clearance and lower the risk of CVD and its progression. Stating can lower CoQ10 levels.

Statins:

- may raise alpha-1 by 10-25%, Statins promote the production of HDL into large particles, such as alpha-1 and alpha-2, Alpha-1 HDL is a large protective form of HDL.
- lowering CRP with statin therapy has been shown to lower CVD events. Elevated CRP may indicate inflammation and CVD risk.

### Niacin

Consensus guidelines recommend monitoring glycemic control after initiating niacin (nicotinic acid) treatment or increasing its dosage.

Niacin:

- may promote the maturation of HDL into large particles, such as alpha-1 and alpha-2 and their corresponding pre-alpha particles.
- may decrease CRP by 15-24% in patients with stable coronary artery disease and metabolic syndrome.

### **Omega-3 Fatty Acids**

Studies have shown that Omega-3 Fatty Acids are essential to heart health. Their benefits may include improved cholesterol balance, improved immune system function, reduced inflammation and reduced rates of heart disease.

### Omega-3 Fatty Acids:

Omega-3 fatty acids may lower CRP.

To improve Fatty Acid Balance results focus on the dietary changes provided in the Fatty Acid Balance interpretation section of this report. Consuming 1-2 grams of concentrated fish oil daily or 1800 mg of EPA per day has been shown to decrease heart disease morbidity and mortality.

### Notes

The following testing was not completed as it is not performed at BHDx: Tests 1137 Leptin and 98450 Interleukin-6 are not orderable for tis client

### Footnotes

**bost**onheart

The intended use of this report is to provide an aid in the physician's treatment decisions. This report is intended for a physician or other qualified health care provider. Please consult with your physician regarding any questions.

<sup>1</sup> This test was developed and its performance characteristics determined by Boston Heart Diagnostics. It has not been cleared or approved by the U.S. Food and Drug Administration (FDA). The FDA has determined that such clearance is not necessary. This test is used for clinical purposes. It should not be regarded as investigational or for research. Methods: HDL Map: Gel electrophoresis; Cholesterol Balance and Fatty Acid Balance: GC/MS; MPO: Immunoturbidometric; CoQ10: UPLC; Adiponectin: Latex turbidimetric immunoassay; OxPL-apoB: Chemiluminescent immunoassay; LDL-P: NMR. TMAO, Cortisol, DHEA-S, DHT, Estradiol, Estrone, Progesterone, Total Testosterone, Estriol, 170H Progesterone, Androstenedione: LC/MS/MS.

<sup>2</sup>A fasting glucose level of >125 mg/dL indicates the presence of diabetes mellitus, and a fasting glucose level of <70 mg/dL indicates hypoglycemia.

<sup>3</sup>A test result in the low range is normal in a non-diabetic, but low if a patient has diabetes (consistent with diabetes).

<sup>4</sup>Genetic analysis is performed by real time Polymerase Chain Reaction (PCR) using TaqMan• probes. Amplified gene nucleotide sites: APOE - Apolipoprotein E, T471 C rs429358, C609T rs7412; F5 - Coagulation Factor V, G1746A rs6025; F2 - Coagulation Factor 2, G20210A rs1799963; CYP2C19 (Clopidogrel response) -Cytochrome P450 2C19, G681A rs4244275, G636A rs4986893, C-806T rs12248560; SLC01B1 (Statin Myopathy) - Solute Carrier Organic Anion Transporter Family, Member 1B1, T625C rs4149056. MTHFR – Methylenetetrahydrofolate reductase, C677T rs1801133, A1298C rs1801131. Limitations: Other rare mutations not detected by these assays may be present in some individuals.

<sup>6</sup>Test performed at 200 Crossing Boulevard, Framingham, MA 01702. CLIA#: 22D2100622. NYSDOH: 9021.

<sup>9</sup>Biotin concentrations of up to 1200 ng/mL in patient serum have been shown to have no impact on assay results.

<sup>10</sup>High doses of biotin (>5mg/day) may interfere with assay results. Patient assumed to be refraining from biotin supplementation for at least 3 days prior to blood draw.

<sup>11</sup>Our Cholesterol Balance Test was modified on April 1, 2019. This modification has resulted in new reference ranges. Results reported prior to April 1, 2019 should not be compared with results from this date forward.

\* Tests performed with alternative methodologies are not displayed for comparative purposes.

🔺 = Critical Value, 🕰 = Alert Value, TNP = Test Not Performed, PEND = Test Result Pending, GSP = Glycated Serum Protein, ADA = American Diabetes Association
